

What makes parties adapt to voter preferences? The role of party organisation, goals and ideology

DANIEL BISCHOF AND MARKUS WAGNER*

The landmark study by Adams et al. (2006) finds that niche parties are unresponsive to the median voter and provides two theoretical reasons for this pattern: these parties are (1) more policy-seeking and (2) more influenced by their activists. Recent research adds that niche parties have narrow issue appeals beyond the traditional left-right dimension, implying that these parties pay less attention to the left-right median voter. We test these three mechanisms in a replication and extension of the original findings by Adams et al. (2006). We find that policy-seeking parties and parties with a narrow issue focus are less likely to track median voter changes, while activist influence has no moderating effect. This finding has important implications for our understanding of party responsiveness.

WHY ARE NICHE PARTIES LESS RESPONSIVE TO PUBLIC OPINION SHIFTS?

A landmark finding in recent research on party competition has been that parties differ in how they react to public opinion shifts.¹ In their influential study Adams et al. (2006) find that niche parties – which they define as Communist, Green and radical-right parties – fail to track changes in the median voter position, while other, mainstream parties do. However, they do not argue that there was something inherent to these three party families that makes them less likely to follow changes in the median voter position. Instead, they suggest that these three party families tend to prioritise policy over office and tend to be activist-led. They argue that these two features explain why these parties would not track the median voter. In this research note, we replicate and extend their analysis but replace their simple dichotomy based on party families with the party differences that they argue drive the pattern they find: party goals and party organisation. We also add a third aspect of niche parties not alluded to by Adams et al. (2006), party ideology, specifically the extent to which parties focus on niche issues. All three of these mechanisms may contribute to the pattern they found. Our analysis examines how these three aspects of parties act as mechanisms connecting median voter change to party policy change and thereby contributes to the ongoing scholarly debate on the party characteristics that drive party responsiveness to voters.

Following Adams et al. (2006), the first mechanism why some parties fail to track the median voter is that they are more policy-seeking than others: they prioritise their policy objectives over winning votes or gaining office. Adams et al. (2006, 514-515) suggest this mechanism as an underlying difference between niche parties and other parties. They also argue that niche parties have a longer time horizon concerning the goals they wish to achieve, as their aim is to build up the party over the long term rather than maximising support in the next election. The policy focus of some parties explains why they do not respond to voter shifts, since their aim is not to increase

*We thank Jim Adams, Simon Bornschieer, Moritz Marbach, Thomas Meyer and the participants of the University of Zurich publication seminar for excellent feedback on earlier drafts of this paper. We also want to thank Jim Adams, Lawrence Ezrow and Garrett Glasgow for sharing their data and analysis files with us. The excellent feedback of three anonymous reviewers significantly helped us to improve the quality of this paper. All remaining errors are our own. A supplementary online appendix and replication data and code are available at <http://journals.cambridge.org/action/displayJournal?jid=JPS>.

¹Adams et al. 2006; Adams, Haupt, and Stoll 2008; Schumacher, Vries, and Vis 2013.

support per se, but to increase support for implementing their policy goals. Giving up on policy aims for electoral gains would go against the *raison d'être* of the party. Hence, we would expect policy-seeking parties to be less likely to track shifts in median voter positions than vote- and office-seeking parties (*policy-seeking hypothesis*, H1).

The second mechanism is that some parties are more hamstrung by their activists. Adams et al. (2006, 515) cite Kitschelt (1994) and D'Alimonte (1999) in claiming that 'niche parties' activists are strongly policy oriented and are therefore highly resistant to ideological "compromises" in their party's policies'. In this view, niche party elites stick with their policy proposals in order to avoid demobilising activists and damaging the party's reputation for competence and reliability. In other words, activists in niche parties have a strong influence on party policy, limiting party elites' ability to shift positions in line with the median voter. Related research shows that parties whose leaders are chosen by rank-and-file members or whose activists have greater influence are less likely to follow the median voter position and more likely to track that of their own supporters.² Our second hypothesis is thus that parties with a strong activist base are less likely to track shifts in median voter positions than parties with a strong leadership (*activist influence hypothesis*, H2).

Finally, and going beyond the arguments made by Adams et al. (2006), parties differ in their programmatic profiles, specifically in the distribution of emphasis in their policy programmes. Thus, building on Meguid (2005), scholars suggest that some parties have narrower issue appeals than others;³ these parties have also been termed niche parties, though the definition differs from that put forward by Adams et al. (2006). While mainstream parties tend to address various issues and topics, niche parties focus on one or two key areas, such as immigration, decentralisation or the environment, with additional issues clearly secondary. A niche issue focus should also make parties less likely to follow the median voter on a general left-right dimension. For one, such parties will mostly be interested in their core issue and will therefore pay less attention to public opinion change on the broader left-right dimension. Moreover, ignoring median voter change is unlikely to be costly for these parties, as their reputations are built on their distinctive emphasis and clear position on otherwise secondary issues. Since their electoral success is not built on proximity to the median voter, they have little incentive to follow public opinion, especially on a general left-right dimension. Overall, we expect that parties with a niche issue focus are less likely to track shifts in median voter positions than parties with a broader issue focus (*ideological nicheness hypothesis*, H3).

We therefore identify three reasons why niche parties may fail to update their policy programmes in line with changes in median voter preferences. Adams et al. (2006) used a simple binary indicator based on party families in their analysis, and an empirical correlation between the mechanisms we identify could provide some justification for this decision. However, this empirical correlation remains debated, and the assumption that a dichotomous indicator sufficiently captures party differences is a strong one. Moreover, while Lehrer (2012) shows that Communist, Green and radical-right parties all give activists key internal power, Schumacher, Vries, and Vis (2013) argue that many radical-right parties, for instance the Front National, are leadership-dominated. We provide evidence on the empirical correlation between our mechanisms below.

Even if there are empirical correlations between the mechanisms, it is important that at least in principle these three party characteristics can vary independently of each other. For example, activists are not necessarily opposed to tracking changes in the preferences of the median voter. Adams et al. (2006) themselves argue that activist influence is only a hindrance to vote-seeking

²Lehrer 2012; Meyer 2013; Schumacher, Vries, and Vis 2013.

³Wagner 2012; Meyer and Miller 2015; Bischof 2015; Greene 2015.

strategies if party activists are particularly policy-seeking. Parties with strong activist influence could still track the median voter if activists also endorse vote-seeking strategies. As Kitschelt (1994) points out, it is actually quite common for activists to be vote-seeking.⁴ He cautions against a simple opposition of activists and leaders and argues that leaders can sometimes be stubborn policy-seekers, while activists can sometimes support vote-seeking compromises. Hence, activist influence might not be a likely mechanism underlying the pattern found in Adams et al. 2006. To take a second example, parties with a narrow issue focus need not necessarily be more policy-seeking than other parties. In fact, in the past catch-all parties such as Social Democratic parties were characterized by high policy stability.⁵ Hence, our aim is to establish the distinct influence of each mechanism – policy-seeking, activist influence and narrow issue focus – on the phenomenon uncovered by Adams et al. (2006); in doing so, we go beyond existing research on some of these mechanisms.⁶ We begin by describing how we measure each mechanism.

MEASURING THE MECHANISMS

We measure policy-seeking and activist influence using the expert survey data collected by Laver and Hunt (1992). This data was collected in 1989 and asked experts from each country to assess party positions and party characteristics. To assess policy-seeking, experts were asked to rate the extent to which each party prioritises policy over office. The precise question posed to experts was: ‘Forced to make a choice, would party leaders give up policy objectives in order to get into government or would they sacrifice a place in government in order to maintain policy objectives?’ The scale provided runs from 1 to 20; we reverse the original scale so ‘1’ indicates maximum willingness to prioritise office and ‘20’ maximum willingness to prioritise policy. This scale has also been used in recent research by Pedersen (2012).

To assess activist influence, the same experts were asked to rate the influence of activists and the leadership on party policy, using two scales again ranging from 1 to 20. The first scale asked experts to assess the power of the party leadership, the second that of party activists, with 1 indicating ‘no influence at all’ and 20 ‘great influence’. We create a scale by subtracting leadership influence from activist influence, in line with recent research by Schumacher, Vries, and Vis (2013), Wagner and Meyer (2014) and Schumacher (2015). The combined scale ranges from -15 to 7.3, with higher scores indicating greater activist influence and a score of 0 indicating equal influence.⁷

Unfortunately, the Laver-Hunt measures are only available for one timepoint, while the Adams et al. data cover the period until 1998. Thus, changes in party organisation might have occurred which are not reflected in the Laver-Hunt measures. However, the measures are arguably still far more nuanced than the basic binary niche-mainstream dichotomy employed by Adams et al. (2006). Moreover, it has been noted that party organisation is relatively stable over time.⁸ While later measures of activist influence exist⁹, these assessments refer to time periods well after 1998, when the Adams et al. dataset of median voter positions ends. Lehrer (2012) provides evidence on the influence of activists using leadership selection mechanisms, but our measure provides a

⁹E.g. Kitschelt and Freeze 2011.

broader assessment of activist influence¹⁰; moreover, Lehrer himself argues that his measure is intrinsically related to policy-seeking party motivations. Like Schumacher, Vries, and Vis (2013), we therefore believe that these two measures provide the best information we have on party goals and party organisation in the period Adams et al. (2006) study (1976-1998).

To measure a party's niche issue focus, we use Bischof's measure.¹¹ Bischof suggests that niche parties are best understood as (a) predominantly competing on market segments neglected by their competitors and (b) addressing only a narrow range of these segments. His measure builds on Wagner's (2012) and Meyer and Miller's (2015) work but introduces an explicit measure of the narrowness of party platforms and derives specific niche segments measured based on manifesto project data.¹² One key difference to the measure suggested by Meyer and Miller (2015) is that, like Wagner 2012, Bischof argues that niche parties by definition do not compete on economic issues. We use his methodological approach to estimate the nicheness of all parties included in Adams et al.'s study, hence using the same manifesto data Adams et al. use to estimate left-right positions. Bischof derives two measures to empirically assess the nicheness of parties. First, based on standard deviations of issue salience, he measures how neglected a party's issue profile is by its competitors.¹³ Second, building on Shannon's entropy, he measures how narrow a parties' issue profile is.¹⁴ Finally, he combines this two measures in an additive index, with higher values indicating a higher "nicheness" party profile. Because his measure allows parties to change over time, it is more useful than approaches that simply code party families as either having niche issue emphases or not.¹⁵ For example, Communist parties mainly compete on economic issues, albeit often by placing themselves on the extreme left. In contrast to Adams et al., Bischof therefore suggests that Communist parties should in most instances be understood as mainstream parties, not as niche parties.¹⁶ Figure 1 shows a boxplot of nicheness values across party families for the sample used in Adams et al. (2006). Note that Bischof's measure reports that Communist parties' nicheness tends to be comparable to the platforms of traditional mainstream parties (e.g. Liberal and Conservative parties). A t-test reveals that there is no statistically significant difference in the mean levels of Bischof's nicheness measure for Adams et al.'s niche and mainstream parties.¹⁷ In addition, there is only a very weak correlation between Bischof's nicheness measure and the party goals and organisation measures derived from the Laver & Hunt studies.¹⁸ These weak correlations suggest that Bischof's measure is not only conceptually distinct from Adams' measure, but also appears to empirically measure distinct party characteristics not directly captured in any of the remaining measures we employ.¹⁹

MODELS AND RESULTS

Our analyses use the data presented in Adams et al. (2006) and subsequently also extend their analysis up until 2015. The data is mostly derived from manifesto project data²¹ and includes parties in eight Western European countries across approximately twenty years (1976–1994).²²

To measure party positions, Adams et al. use the general left-right scale (rile) provided in the manifesto project data; for voter positions, they use average left-right placements as reported in the Eurobarometer surveys. They control for the party’s policy shift in the previous election (the lagged dependent variable), parties’ previous’ vote share change, as well as the interaction between the two variables. We specify the same model as outlined in Adams et al. (2006, 517-518):

$$\begin{aligned}
 \Delta p_{jt} = & b_0 + b_1(\Delta v_t) \\
 & + b_2(\text{Niche}) + b_3(\Delta v_t \times \text{Niche}) \\
 & + b_4(\Delta p_{jt-1}) + b_5(vs_{jt-1}) + b_6(\Delta p_{jt-1} \times vs_{jt-1}) + \\
 & \text{Country FE} + \epsilon_{jt},
 \end{aligned}
 \tag{1}$$

where p is the position of the party, v is the median voter position, $Niche$ is a dummy capturing a party’s niche-mainstream status, vs is the party’s vote share, j is the party and t is the election. In the subsequent models, $Niche$ is replaced by the three measures outlined above to test the three mechanisms we proposed in the last section.²³ To account for the specific panel structure

²¹Budge et al. 2001; Klingemann et al. 2006; Volkens et al. 2012.

²²Please consult Table A.3 in the Appendix for a detailed overview of the parties and elections covered in the dataset.

²³Unfortunately, party goals were not assessed by Laver and Hunt’s experts for Spain. Thus, we excluded Spain from our analysis to ensure comparability of our results across models. Note that our findings do not change if Spain is included for the models assessing the activist influence and ideological nicheness hypothesis.

of the data, we follow Adams et al. and rely (as noted above) on a lagged dependent variable (Δp_{jt-1}), introduce country fixed effects and cluster standard errors by election to control for autocorrelation, country-specific factors and contemporaneous correlation respectively.

We present the full results of each model in Table 1 (columns 1-4). To ease interpretation of the interaction terms, we present the marginal effects of each interaction to correctly interpret the fully-specified effect of our interactions in Figure 2.²⁴ We can see that the various measures all have similar substantive effects: mainstream parties, office-seeking parties and parties with a broad issue focus are more likely to follow the median voter, while niche parties, policy-seeking parties and those with a narrow issue focus fail to respond to the median voter. At the same time, we only find statistically significant effects at the 0.05 level for the Adams et al. and Bischof models, though the interaction effect for the policy-seeking model is significant at the 0.1 level as well.²⁵ Looking at the marginal effects plots reveals that the slopes of the interaction between the activist and policy-seeking variables are flatter than for the Bischof model. Furthermore, both interactions are not significant for most empirically observed values of the policy-seeking and party organization measures, respectively. Thus, we find some evidence supporting the *policy-seeking hypothesis* and very weak evidence for the *activist influence hypothesis*, while we find clear evidence for the *ideological nicheness hypothesis*.²⁶

Since Bischof's measure is also two-dimensional – measuring issue nicheness and issue specialization in a single index – we conducted further analyses, reported in Table A.5 in the Appendix. In this analysis, we split Bischof's measure and estimate the effect of both nicheness and specialisation on parties' responsiveness to public opinion shifts. Both measures report a negative interaction with public opinion shifts. However, only the interaction between parties' nicheness and public opinion shifts is statistically significant at conventional levels. Thus, it appears to be more important that a party occupies an ideological niche than that it is ideologically specialised; focusing on non-economic issues neglected by competitors more strongly conditions party left-right responsiveness to the median voter than specialising on a small set of these issues. In sum, employing Bischof's measure lends support for our theoretical suggestion that parties with a niche issue focus are less responsive to the median voter. As suggested in our theoretical discussion, parties with a strong focus on niche issues might feel less obligated to adapt to mean voter preferences on the general left-right scale as a means of ensuring electoral success.

Finally, Table 2 reports the findings for an extended time series (1976-2015), almost doubling the period and cases covered. We do not include the Laver-Hunt expert survey measures in these models since extrapolating from 1989 assessments to today is questionable. In these Models, the simple niche party dichotomous variable used by Adams et al. no longer shows a conventionally significant interaction with public opinion shifts, though the effect continues to be in the right direction. There is a moderating effect for nicheness as measured by Bischof even when we also control for the Adams et al. niche party indicator as well as its interaction with public

²⁴Brambor, Clark, and Golder 2005, 65.

²⁵A second set of models reported in the Appendix provides robustness tests and includes various combinations of all three party characteristics and their interactions with public opinion shifts (Table A.4). The findings reported above remain robust in these models. Notice, however, that we do not find significant effects if we include an interaction between both Adams et al.'s measure and Bischof's measure with public opinion shift, at least for the time period captured in Adams et al.'s study; note that significant effects are nevertheless found in the extended dataset presented in Table 2 below.

²⁶Further analysis indicates that parties with strong activist influence may indeed track the median voter if activists also endorse vote-seeking strategies. Model (4) in Table A.4 in the Appendix includes the three-way interaction 'activist influence \times office-seeking \times public opinion shift'. While the three-way interaction term is not statistically significant at conventional levels, its p-value is close to .1. Marginal effects show some evidence of a tendency for parties with strong activists to fail to track the median voter if the party is generally policy-seeking, whereas parties with strong activists and a vote-seeking orientation do track the median voter.

opinion shifts. Further analysis reveals that the difference in nicheness (as measured using Bischof's approach) between Adams at al.'s mainstream and niche parties increased substantially in the extended period, a development which is not captured in the categorisation based on party families.

The substantive effect of party characteristics

To enhance our understanding of the substantive effect of our results, we estimate simulations of counterfactual scenarios.²⁷ The regression results (specifically the coefficients and standard errors) reported in the last section rely on the number of observations included in our analysis. Yet, reporting regression results as point estimates (as in Table 1) or calculating derivatives (as in Figure 2) ignores the estimation uncertainty stemming from the fact that we observe fewer than infinite number of observations.²⁸ In contrast, simulations allow us to estimate, report and investigate more carefully the uncertainties associated with our regression estimates.²⁹

Figure 3: Distributions of simulations for factual & counterfactual nicheness

Source: Authors' own.

Note: Simulations based on 1,000 draws from a multivariate normal distribution defined by the coefficients and covariance matrix reported in table 1.

The Front National in 1993 is a useful example to base our simulations on, since the data report it to be a policy-seeking party with a narrow issue appeal. Furthermore, by choosing an

²⁸King, Tomz, and Wittenberg 2000, 348-349.

²⁹349-351.

election that is close in time (1993) to Laver and Hunt's expert survey (1989), we ensure that the policy-seeking variable is closely related to the actual policy-seeking ambitions of the Front National in 1993.

We simulate several scenarios in which we change the *factual* characteristics of the Front National into relevant *counterfactual* scenarios.³⁰ To do so we first took 1,000 random draws from a multivariate normal distribution defined by the coefficients and covariance matrix from the regression models reported in Table 1. Second, we calculated linear predictions of our dependent variable (party position shift) based on the actual characteristics of the Front National. Third, we changed the party characteristics of the Front National in the various models to reflect three counterfactual scenarios. We varied all three party characteristics to take on the values at the 10th percentile, the median and the 90th percentile.

Figure 3 reports the results of these simulations. Public opinion shifted towards the left in France in 1993. Thus, a negative prediction in Figure 3 can be interpreted as a responsive shift towards public opinion. In contrast, a positive value on the x-axis in Figure 3 suggests that the Front National shifted away from the public sentiment in France. In the actual data, the Front National shifted away from the median voter and towards the extreme right.

The simulations underline the previous result that all three mechanisms affect party position shifts in the theorised direction. Yet, it becomes apparent that the magnitude of the effects differ. Changing the variable from the 10th percentile to the 90th percentile has a clear effect for party nicheness, while differences are much smaller for party goals and activist influence. The distributions for these two variables at the 10th percentile and the 90th percentile largely overlap. A second implication of these simulations is that high levels of nicheness imply that parties move in the opposite direction of the median voter, while policy-seeking and activist-oriented parties are more likely just to stay put. This is visible when comparing the positions of the distributions at the the 10% percentile, which for party goals and organisation more often include 0, which is the value indicating that a party stays put and does not move to the left nor the right. Finally, both policy-seeking and party organisation show somewhat larger levels of uncertainty than Bischof's nicheness measure. Overall, the simulations again show that nicheness has the clearest moderating effect, while evidence for party goals and organisation is consistent with expectations, if weaker.

CONCLUSION

Overall, our results are partly in line with one of the mechanisms proposed by Adams et al. (2006): there is some evidence that parties that are more policy-seeking are less likely to track changes in the median voter position. We also add to their finding by showing that parties focusing on issues neglected by competitors, which is how many researchers now define niche parties, are also less likely to follow changes in the preferences of the left-right median voter. However, we do not find that parties with a stronger activist influence are less likely to track the median voter, though this may partly depend on how accepting of vote-seeking this activist base is.³¹

Our findings have implications for the study of party competition. For one, it is useful to see that the simple binary coding by Adams et al. (2006) does to a certain extent capture essential patterns in how parties compete. When replacing their measure with more nuanced ones, we arrive at similar results for all three mechanisms in terms of the direction of association, though

³⁰349-350.

³¹See also Schumacher, Vries, and Vis 2013; Lehrer 2012.

findings are strongest and clearest for policy-seeking and niche issue focus. At the same time, the empirical and theoretical linkages between party organisation and party goals also make it difficult to conclusively isolate the one feature of parties that most strongly drives responses to median voter positions. In a similar vein, Lehrer (2012) suggests that the electoral strategies of niche parties differ from those of mainstream parties as they have more inclusive membership structures, which in turn reflect greater policy-seeking orientation. One interpretation of our results is that the findings presented by Lehrer (2012) are driven more by institutionally-enshrined policy-seeking than by actual activist influence. Since current data availability, especially for measures of party organisation, is limited, we would urge future data collection and research that applies the different measures to a broader set of cases.³²

Even though our results show that binary distinctions between types of parties do capture some aspects of party competition, we should rather strive to include the relevant mechanisms directly rather than relying on simpler measures. Access to relevant data and measures is becoming ever easier; specifically, the nicheness measures employed in this paper can be easily accessed in statistical software, e.g. R, while new or extended measures of party organisation are available in Schumacher and Giger (2017) and Rohrschneider and Whitefield (2012).³³ If researchers' hypotheses suggest that a specific party characteristic underlies strategies, they should try to measure and include that characteristic. Future data collection efforts should do more in this regard, even if doing so is challenging.
